Fuel Polishing

Overtime your fuel tank may become contaminated by things such as water, particulates, and bacteria. Fuel polishing is a process used to clean the fuel by lowering the overall contaminant levels within the tank, this effectively brings the fuel back into specification and ready to use.

In fuel polishing we use the fuel itself is recirculated it within the tank which creates a turbulent force that agitate most common types of contamination found within the tank, throughout this process the fuel is continually passed through purification media removing the contaminants and returning clean fuel to the tank.

This cleaning process is carried out when there is fuel still within the tank and will not require emergency or critical systems to be taken offline.
